Madrid, September 2010
Research Project outline

• Introduction and objectives
• Validation of the PeneloPET code
• Factors affecting Sensitivity, Noise equivalent count rate (NEC), Scatter fraction and Time-of-flight (TOF)
• TOF characterization
• Conclusions
PET Physics

2 photons of 511 keV in coincidence, coming in a straight line from the same annihilation.

unstable nucleus -> emits positron -> positron annihilates with electron -> two 511 keV photons are emitted simultaneously in opposite directions.
Clinical PET Imaging

- Inject radiotracer
- Detect (scintillation detectors) two annihilation photons in coincidence.
- Defines line along which annihilation lies
- Use reconstruction algorithms to compute image of radiotracer distribution using all the different angular views.
- Analyze data
Types of Coincidences

- **True coincidence** This event occurs when both annihilation photons reached detectors without being scatter in the patient and both photons are successfully detected.
- **Scatter coincidence** is when one or both photons from a single event are scattered and both are detected.
- **Random coincidence** They arise when two unrelated photons are detected in opposing detectors.
Noise equivalent count rate (NEC)

The NEC rate is a global measure of scanner count rate performance which takes into account that a fraction of counts (scatter and random coincidences) do not contribute to the quality of the images.

\[ NEC = \frac{T^2}{(T + S + R)} \]

Scatter Fraction (SF)

The proportion of accepted coincidences which have undergone Compton scattering prior to detection is called a scatter fraction (SF).

\[ SF = \frac{S}{T+S+R} \times 100 \]
Time of Flight (TOF)

The annihilation position can be estimated by determining the difference in time arrival of the two photons.

Time-of-flight difference ($\Delta t$) is immediately related to the distance of the annihilation point from the center of the line of response (LOR) by:

$$\delta \Delta t = 2 \times \delta \Delta x / c$$
Objectives

- Validate of PeneloPET simulation for clinical Biograph (Sensitivity, Noise equivalent count rate (NEC) and scatter fraction (SF)) (Jakoby et al. 2009)
- Study the factors which affect the sensitivity, NEC, scatter fraction and Time-of-Flight (TOF)
Biograph PET/CT with TrueV

- Cylinder scanner geometry
- 4 rings of 48 blocks of 13 x 13 LSO
  4 mm x 4 mm x 20 mm pixels
- 32,448 individual pixels
- 109 transaxial image planes
- 21.8 cm axial field-of-view

- Patient port: 70 cm
- Timing window: 4.5 ns
- NEC: 161 Kcps
- Energy windows 425-650 keV

Total PET scan duration: 3 min.
PeneloPET simulation

PeneloPET is a Monte Carlo code based on PENELOPE, which allows fast and easy simulation of common PET scanners (España et al. 2009).

The basic components of the peneloPET simulation are the definition of detector geometry, source and object.

Validation of the PeneloPET NEC and SF

Input data

The energy window, coincidence time window, and energy resolution are chosen to match the experimental system performed by (Jakoby et al. 2009).

- Detector ring diameter (mm): 824
- Axial FOV (mm): 218
- Energy window (keV): 450 - 650
- Coincidence time window (ns): 4.5 (2.25 ±)
- Energy resolution (%): 14
- Integration time (ns): 120
- Single-detector dead time (ns): 10
- Coincidence dead time (ns): 80
Validation of the PeneloPET NEC and SF

A good agreement between the simulated and experimental results of Jakoby et al (2009)

The sensitivity increases with the crystal length linearly up to 3 cm, and beyond that we see saturation, because as most of the photons are detected, no further increase of the sensitivity.

The larger the detector crystal size the more sensitivity.
Energy resolution measured the precision with which the system can determine the energy deposited by incident photons. It is measured by histograming the energy of the events acquired and plotting the number of events versus the energy measured.

\[
ER(\%) = \frac{FWHM}{Centroid} \times 100
\]
Factors affecting Sensitivity, NEC and Scatter fraction

As we increase the time window, the count rate decreases. This is due to the loss of many events during the longer processing time of the detector.
• Scatter fraction can be measured at low activity where the randoms are negligible (NEMA, N-2, 2007).

### Lower energy window

More scatter events are rejected initially through the use of higher LLD and the result is that the fraction of true coincidence events involving scatter that are processed is lower.

</tbody>
</table>
Low energy window will have an effect of the counts rate due to number of scatter events
The simulation output is in good agreement with the calculated values.

Validation of the PeneloPET TOF Simulation with TOF resolution

\[ \Delta t = \frac{5 \times 2}{30} = 0.33 \text{ ns} \]

* Distance from the center of line of response (LOR)
TOF resolution would allow determining the position of the source within a distance;

\[ \Delta x = \frac{c}{2} \div \Delta t \]

\[ \Delta t = 2 \times \Delta x / c \]

\[ c = 2.998 \text{ cm/ns} \]

550 ps timing resolution

\[ \Rightarrow 8.24 \text{ cm localization} \]

\[ \Delta x = 2.998 \times 10^{10} \text{ cm/s} \times 550 \times 10^{-12} \text{s} / 2 \]

= 8.24 cm.
Crystal rise time

- At rise time below 800 ps there is no change with the time resolution, where at the rise time of greater than 800 ps, as the crystal rise time increases also time resolution increases.
In this work we validated peneloPET simulation for Biograph (B-TPTV) PET. The output data of the peneloPET simulations have a good agreement with both calculated and experimental results of the NEC, scatter fraction and TOF.

The validation of PeneloPET simulations would allow to use these simulations to study the effect of changing the geometry of the scanner (adding extra rings), as well as to study the impact in the reconstruction of using different TOF windows. This will be the goal for a further study.

In general PeneloPET emerges as a powerful tool for clinical PET simulations.
